

Black Holes I — Exercise sheet 1

(1.1) Newtonian black holes

Describe mathematically what happens when you send a light-ray from the surface of a Newtonian black hole outward. By “Newtonian black hole” I mean a star whose escape velocity exceeds the speed of light, but that is nevertheless described by Newtonian physics [note: as far as we know such stars do not exist in Nature — so this exercise is a Gedankenexperiment]. Discuss in what sense this star really is “black”, and how mass and radius have to be related.

(1.2) The unbearable weakness of gravity

Compare the Coulomb force with the gravitational force, by considering a Hydrogen atom. More concretely, calculate the electrostatic force and the gravitational force between a proton and an electron, separated at a distance of an Ångstrom. How heavy would a proton have to be so that its Coulomb potential equals to its Newtonian potential? If you want, answer also the following questions: (why) is gravity negligible in particle physics? (why) are all other forces besides gravity negligible in the solar system?

(1.3) Natural units

Natural units are physical units where for convenience various conversion factors introduced by humans are set to unity: $c = \hbar = G_N = k_B = 1$, where c is Einstein’s constant (vacuum speed of light), \hbar is Planck’s constant, G_N is Newton’s constant and k_B is Boltzmann’s constant. Calculate the following quantities in natural units: age of the Universe, radius of visible Universe, cosmological constant, mass of the Sun, mass of the proton, mass of a human cell, the current room temperature and, if you want, miscellaneous further quantities like your age, your mass, your height etc. Compare the simplicity of the results with the same results expressed in some “unnatural units”, e.g. the ones used on a ship, where time is measured in seconds, speed in knots, vertical lengths in meters, horizontal lengths in sea miles, and so on.

These exercises are due on October 12th 2009.

Hints:

- For the first example you need Newton's gravity law and classical mechanics. It is a bit simpler (but not necessary) to work with energies.
- For the second example you need Newton's gravity and Coulomb's law.
- For the third example you need the values of various conversion factors. You can google them up or find them in most textbooks.
